Abstract. This paper is a study of the knowledge-sharing difficulties experienced by three departments in a knowledge-intensive firm. The case organisation is a global consulting firm that has been on the forefront of knowledge management and has won several knowledge management related international acclaims. Our analysis shows that there are strong disincentives in place for departments to share knowledge. We found that the nature of the businesses of the departments was very different and so were their knowledge requirements and their preferred ways to seek knowledge. Additionally, confidentiality agreements with clients and lack of cross-departmental interaction inhibited knowledge sharing outside departmental boundaries. Contrary to the common belief in the organisation, we found that one single IT system could not satisfy the context-specific knowledge-sharing needs of the different departments. We suggest that some very recent breakthrough technologies could be applied to facilitate cross-departmental knowledge sharing provided they are implemented at the strategic organisational level.

Keywords: Knowledge sharing; knowledge management systems; knowledge codification; knowledge personalisation; consulting companies.

1. Introduction

To be successful at the present time, it is imperative for global consulting companies to be knowledge intensive, apply reuse economics, create knowledge and deliver quality to keep pace with constant change. They need to harness knowledge and learn faster than competition. In order to achieve that, they need to effectively and efficiently organise and manage the processes of knowledge sharing internally in the organisation.

In the context of this paper, “knowledge” will be taken to mean “a fluid mix of framed experience, values, contextual information, and expert insight that provides a framework for evaluating and incorporating new experiences and information” (Davenport and Prusak, 1998, 3.5). We adopt the definition of “knowledge sharing” as providing one’s knowledge to others as well as receiving knowledge from others (Davenport and Prusak, 1998).

Knowledge sharing among departments within the same organisation is in reality not as natural as it may appear at first glance. It is an ungrounded assumption that departments will share the knowledge they possess with others or tap into the collective corporate knowledge base in order to find a solution to their problem merely because such systems have been made available to them (Sbarcea, 2001). Instead, knowledge-sharing hostility is a phenomenon that widely dominates organisational reality (Husted and Michailova, 2002).

There are various difficulties in the process of knowledge sharing. First, knowledge is developed from the local level, e.g., by definition, knowledge sharing is embedded in a certain cognitive and behavioural context. Without understanding the context, one cannot inquire into the reasoning and the assumptions behind the particular piece of knowledge. Second, knowledge is asymmetrically distributed in any organisation. Often those who possess the knowledge are not inclined to invest time and effort to share it without expecting reciprocity, as resources are finite and scarce (Davenport and Prusak, 1998; O’Dell and Grayson, 1998). Third, knowledge sharing is voluntary (Dixon, 2002) and efficient knowledge sharing depends on the willingness of individuals to identify the knowledge they possess and to share knowledge when required (Nonaka, 1994). Knowledge sharing involves direct commitment from both transmitter and receiver. If the potential knowledge transmitter is not aware that someone in
The organisation would be interested in the knowledge she or he possesses, she or he will not actively share this knowledge. Similarly, if the potential receiver is not aware of the existence of a particular piece of knowledge, she or he will not be able to seek it (Bouty, 2000). As human behaviour is inherently opportunistic, adverse selection and moral hazard may influence the individual’s motivation to share knowledge in a negative manner. Moreover, an individual’s ability to appreciate new knowledge is a function of their “absorptive capacity” (Cohen and Levinthal, 1990).

The present paper focuses on the difficulties of knowledge sharing across departments within the Copenhagen branch of a global consulting company. The rest of the paper is organised as follows. First, we introduce the studied organisation. We then present and discuss our data collection methods. We introduce a few selected theoretical frameworks and utilise them in the analysis of our empirical data. We conclude the paper by summing up the key points of our analysis and by suggesting solutions to the identified knowledge-sharing challenges.

2. The Studied Organisation and Its Knowledge-Sharing Challenges

ConCop (ConsultCopenhagen) is a fictional name for the Copenhagen branch of a large global consulting company (referred to here as ConGlobal). The Copenhagen branch is a part of the Danish branch, which belongs to the Northern Europe office, which, in turn, is a part of ConGlobal. ConGlobal has been on the knowledge-management (KM) forefront since the beginning of the 1990s. It has several hundred full-time employees to manage its knowledge programs and over the years has received a number of awards as recognition of its KM-related activities.

The aim of KM as defined at ConGlobal is supporting the overall strategy of the company, becoming recognised for delivering value to clients. Proper pursuit of this vision encompasses definition and fulfillment of different roles and functions, both internally, at the established Business Knowledge Center, and externally, in terms of assigning knowledge managers in different business units of the company. The existing knowledge management system (KMS) involves an organisation-wide focus and offers a way to integrate management tools like total quality management, business process reengineering and organisational learning in the pursuit of innovativeness, flexibility and creating and maintaining competitive advantage in an increasingly dynamic business environment. The underlying premise of the KMS is that it will meet expectations of senior management for return on investment or increased effectiveness. Consequently, the KMS is championed by senior general managers in the company and not by senior Information Systems managers.

ConCop employs 500 people. Our study focuses on three departments: Finance Department (FD), Audit Department (AD) and Mentor services department (MD). FD provides mergers and acquisitions services and other advisory services. AD provides audit and business advisory services. MD services is a relatively new department, established a few years ago to help grow starting-up companies by tapping into ConGlobal’s worldwide resources. MD services could provide knowledge on venture capital markets to a client company either by stepping on its own experience or by introducing the client to the AD department in order to offer audit services to it. However, due to lack of formal procedures for sharing knowledge of this type, MD services often finds it tough to reach out to AD and FD. AD has wider industry exposure in Denmark than FD. Due to its larger market presence, AD is aware of clients or non-clients requiring FD services. It also conducts in-depth industry analyses. If AD shares their knowledge on industry and targets with FD, FD could derive more business. In turn, FD often comes across clients who can be potential targets for AD. If FD were to share their knowledge on targets with AD, AD could generate more business too.

Despite KM initiatives in ConGlobal, there is a definite disconnect in the flow of knowledge between FD, MD and AD. Each department can see tremendous benefits from potential knowledge sharing and yet the latter does not take place. The departments recognise that their resources are often being employed on similar tasks at different points in time, which leads to additional costs and lower revenues.

3. Empirical Data Collection

Our data collection started with getting access to and studying extensive written material available on KM in ConCop. We have used policy statements and other documents as a starting point for understanding the current KM structure, its utility and limitations.

Another important source of empirical data was observations as one of the authors was given the opportunity to spend 3 months in ConCop and study the company’s KM activities. This allowed us to study knowledge-sharing in the real context of the organisation, in real time, and without the prompting of potential distortions (or discomfort) from post hoc verbal descriptions (Lee, 1999). The participant as observer (Burgess, 1984; Waddington, 1994) role was adopted as the researcher participated fully in the organisational life but overtly as a researcher.
Conducting individual face-to-face interviews was at the heart of the data collection process. In the context of the studied organisation, the choice of the word “interview” was not most appropriate: since many knowledge-sharing issues border on organisation culture and strategic direction, the interviewee can be confidential or apprehensive of the questions put forward and his or her replies. Therefore, in both internal mails and phone calls we always referred to “discussions on knowledge sharing”, not “interviews”. The discussions were conducted by one of the authors using an interview guide. The interview guide was designed as a questionnaire that was filled during the discussion by the interviewer. In the questionnaire a high degree of structuring, standardising and formalising was utilised, which has facilitated the data analysis. After filling out the questionnaire the interviewee was asked to attest his or her replies.

We opted to have middle managers as our primary respondents for two main reasons. First, in ConCop the existing KMSs are predominantly IT systems and middle managers utilise these systems most. Second, we expected to get a more realistic picture on knowledge sharing from the middle managers rather than from top-level executives since the latter ones tend to stick to official statements and “espoused values” rather than to the actual situation and “values in use”.

Two main rounds of discussions were performed. The first round was explorative, with the purpose of identifying the relevant issues of investigation. These discussions were mainly with people from the Knowledge Center and the Human Resources Department. The second round was designed to more specifically uncover the issues involved in the usage of knowledge web and knowledge databases in the company. All 21 interviews were tape-recorded. In case of any additional clarifications needed, the interviewer discussed them in a subsequent informal session with the interviewee.

4. Distributed Knowledge

Knowledge is created by individuals and bounded by their mental models and reality perception. Knowledge is also deeply rooted in action and in an individual’s commitment to a specific context — a craft or profession, a particular technology or product market, or the activities of a work group or a team (Nonaka et al., 2000). While working in a team, part of the knowledge gets shared and goes into forming the “collective mind” (Weick and Roberts, 1993), which lies between rather than within participating individuals (Spender, 1996). The collective mind is manifested in the manner in which individuals inter-relate their actions (Weick and Roberts, 1993). Consequently, a firm can be considered as sum of the participating individuals’ knowledge. Summation produces a shared body of knowledge that, abstracted, externalised, memorised and made available to new members, could survive the departure of original individuals. So, if a firm is considered as a group of teams, the organisational knowledge should be located in the collective mind of these teams. Unless these teams interact, organisational knowledge will remain in the isolated pools of collective mind. Even when the teams interact, the knowledge sharing will be partial because no individuals in the teams possess all knowledge in the collective mind of their team.

Knowledge sharing involves socialization, articulation, combination and internalization (Nonaka et al., 2000). Tacit knowledge sharing is possible only through strong ties (Hansen, 1999). Assuming that a team has strong ties, tacit knowledge created by team members inside each one’s head can be shared through the processes described by Nonaka et al. (2000) among team members. Following Hansen’s (1999) argument, knowledge cannot be shared across the organisation as the team does not have strong ties within the whole organisation. This knowledge will be different from knowledge created in another team and so on. Thus, there will be knowledge pools in the organisation. In Tsoukas’ (1996) framework of distributed knowledge system, ConCop can be seen as a collection of teams, where knowledge systems are decen- tered systems. Consequently, the company’s knowledge cannot be surveyed as a whole: it is not self-contained, inherently indeterminate and continually reconﬁguring.

5. The Codification-Personalisation Dilemma

The initial push for the growth of the interest in KM is associated with the development of IT (Scarbrough et al., 1999). Some scholars (e.g., Knights et al., 1993; Ruhleder, 1995) view knowledge as being inseparable from the development of contemporary technologies. Others have considered technology as an important enabler in KM (Davenport, 1997; O’Dell and Grayson, 1998; Ruggles, 1998) by focusing on sharing explicit knowledge through groupware, databases, portals and other formal knowledge repositories (Zack, 1999). Zolloff (1996) argues that technologies are fully imbuing tasks of every sort and providing even more powerful opportunities for the kind of learning that translates into value creation. A number of assumptions underlying these approaches have, however, been challenged by pointing out that KM relies heavily upon social patterns, practices and processes and goes far beyond computer-based technologies and infrastructures (Coleman, 1998; Davenport...
and Prusak, 1998; Liebowitz, 1999). Empirical evidence on inhibitors to knowledge sharing stresses the importance of behavioural and cultural factors rather than to outline reasons associated with technology (Skyrme and Amidon, 1997; De Long and Fahey, 2000). The emphasis on the role of technology for specifically knowledge codification has also been questioned by Spender (1996) and Tsoukas (1996).

The tension between technology dominance and interpersonal dynamics in knowledge sharing is reflected in the distinction between codification and personalisation (Hansen et al., 1999). The key features of codification and personalisation are summarised in Table 1.

Codification is based on technologies, such as intranets, electronic repositories, databases, etc. Personalisation emphasises knowledge sharing among individuals, groups and organisations through social networking, and/or engaging in “communities of practice” or “epistemic communities” (Hansen et al., 1999; Brown and Duguid, 2000; Wenger, 2000). Social and interpersonal aspects seem to override technology-based and procedural mechanisms in terms of “meaningful KM” (Hansen et al., 1999). McDermott (1999, p. 104) concluded that the great trap in KM is using information management tools and concepts to design KM systems. Hansen (1999) maintained that strong network ties, i.e., ties associated with personal communication, are important for the sharing of tacit knowledge while non-redundant weak ties play an important role in accessing explicit knowledge from elsewhere.

The above pointed distinctions are useful provided there is an unquestionable agreement regarding tacit and explicit knowledge, existing and new knowledge, and weak and strong ties: not in terms of what they mean in general.

but rather what they mean where, when and to whom. What a person or a group may perceive and define as explicit knowledge can well be mentally mapped as tacit by another person or group. Similarly, a group may perceive certain knowledge as new at the same time when another group treats the same piece of knowledge as existing. Finally, what seems to act as a strong tie in one context can well be perceived as a weak one in another context.

6. Knowledge Management Systems: Models 1 and 2
Malhotra (2003) has developed two models of KMSs, referred to as Model 1 and Model 2.

The goal of KMS in Model 1 (Fig. 1) is getting the right information to the right person at the right time (Malhotra, 2003). The underlying assumption is that all relevant knowledge, including tacit knowledge, can be stored in computerised databases, software programs and institutionalised rules and practices. Some additional assumptions are:

- The same knowledge can be re-used by any human mind or computer to re-process the same logic to produce the same outcomes.
- The same outcomes will be needed and delivered again and again through optimal use of input resources.
- The system’s primary objective is to achieve the most efficient means for transferring pre-specified inputs into pre-determined outcomes.
- There is no need for subjective interpretation of information — criticism and conflict must be minimised to achieve conformance and compliance.

According to Malhotra (2003), in Model 2, the construct of knowledge is better represented as intelligence in action as it results from interaction of data, information, rules, procedures, best practices and traits such as attention, motivation, commitment, creativity and innovation (Fig. 2).

![Fig. 1. KMS model 1. (Source: Malhotra, 2003)](attachment:image)

![Fig. 2. KMS model 2. (Source: Malhotra, 2003)](attachment:image)
Malhotra (2003) emphasized that in Model 2 knowledge is represented as active, affective and dynamic rather than being limited to the domain of IT management. Knowledge is active in the sense that it is best understood in action; it is affective as it takes into consideration not only the cognitive and rational dimensions but also emotional dimensions of human decision-making; and it is dynamic as it is based on ongoing reinterpretations of data, information and assumptions. Model 2 provides a better representation of reality as it takes into consideration two key characteristics. First, what is done with data, information and best practices depends upon the subjective interpretation of individuals and groups that transform these inputs into actions and performance. Second, performance outcomes need to be continuously re-assessed to ensure they represent best business performance for the enterprise with respect to changing conditions (Malhotra, 2003).

7. Knowledge Sharing in ConCop: Analysis

We develop the analysis of knowledge sharing in ConCop by taking one of the studied departments, FD, as the knowledge recipient and the other two departments, AD and MD, as knowledge transmitters to FD. Similarly, either AD or MD can be considered as a recipient and the respective analysis can be conducted.

Our analysis suggests that the FD knowledge requirements are of two types: knowledge on targets and knowledge on industry. We have identified the following three knowledge sources:

- Personal networks
  - counterparts in other regional offices of ConGlobal;
  - other industry experts (e.g., old colleagues from university, other companies, etc.);
  - business associates in ConDenmark (outside FD), for instance in AD.
- External sources
- Internal sources (e.g., Knowledge Center reports, community home spaces, etc.).

The major knowledge requirements of FD are met through networks and external sources. AD and MD can provide the knowledge required by FD if they can contribute knowledge on targets or knowledge on industry. As mentioned earlier, AD has broader market exposure and can definitely contribute in the “knowledge on targets” area by providing leads to FD with possible leads to targets. Since AD has broader market exposure to clients, it can also contribute its industry expertise in the “knowledge on industry” area. AD can contribute this “knowledge on industry” either by applying a codification or a personalisation strategy.

MD services can contribute in the “knowledge on targets” area by providing leads to FD of probable targets or leads of people in the network who know the probable clients. FD draws most of its knowledge on targets and industry both from networks and external sources and both AD and MD can contribute to the knowledge FD derives from its networks. Neither AD nor MD can contribute to knowledge from external sources.

If knowledge that will help FD is to be shared, it can be done in one of the following ways:

- Knowledge on industry through codification
- Knowledge on industry through personalisation
- Knowledge on targets through codification
- Knowledge on targets through personalisation

According to all our respondents, knowledge on targets through codification in ConCop is either highly inefficient or not suitable. Regarding the possibility to share knowledge on targets and industry through personalisation, we have observed that FD professionals do not interact with other departments in the firm. Several AD audit professionals admitted that they “do not know anything except that there is a FD office in this house”. Since no systems are involved in this process, the reason for not sharing through personalisation remains to be associated with the single consultants.

AD and FD provide very different services. Consequently, it would be logical to expect that their knowledge requirements will differ too. This issue was clarified in the interviews when audit professionals confirmed to using the internal sources as rarely as FD professionals. Table 2 summarises some of the key differences in business activity between the two departments and lists the implications on knowledge requirements. The comparison is useful in establishing why sharing industry-related knowledge between these two departments through codification is difficult.

As it can be seen from Table 2, FD requires knowledge that is different from AD in at least two dimensions. First, it requires more time-dependent, complex and wider industry knowledge due to its short engagements. Second, it requires better information on its networks both due to its interaction with top management and high involvement services and due to its requirement to remain better informed of the changes in the environment.

Keeping the time constant, AD and FD differ on a number of important dimensions, such as number of industries they deal with, number of sub-sectors they are involved with, number of transactions they conduct and

</table>

number of external actors they interact with. Our discussions with AD and FD managers and our observations on the nature of the business of the two departments lead us conclude that FD is exposed to a more unstable environment with many more unpredictable factors at every point as compared to AD. Utilising Malhotra’s (2003) framework, we argue that FD needs a Model 2-based KMS whereas AD would profit from exercising a Model 1 KMS. This indicates that the KMS is incompetent to handle the dynamic and complex knowledge sharing needed in ConCop.

Furthermore, FD work is more close to a management consulting organisation than to an audit firm. And perhaps it is not a coincidence that most consulting organisations prefer to use a personalisation approach (that can be considered to be much closer to Model 2 KMS) for knowledge sharing. However, we have observed that although AD does not interact regularly with FD, both departments have introduced regular meetings to discuss how business knowledge can be shared. Few interviewees have reported satisfactory progress in this regard. ConGlobal and ConDenmark have urged both departments to share knowledge. Both the industry reports produced by AD and our interviews have established that AD does possess the knowledge needed by FD.

Several interviewees stated that the two KMS models behave as two separate silos in ConCop. As mentioned by a Human Resources manager responsible for launching performance appraisal systems in ConCop, there are no incentives for sharing knowledge or for selling more Type 2 services. Additionally, incorporating incentives for selling Type 2 services will be against the new corporate governance rules being adopted in international business. Discussions with interviewees have led us to conclude that this area constitutes a minefield. Therefore, as a background and support for further discussion, it is essential to consider the following brief from ConGlobal Knowledge Sharing Policy document:

Our clients expect (1) us to bring them our accumulated experience to solve their business problems. (2) They also expect us to maintain the confidentiality of their information. (3) We have an obligation to protect our intellectual assets and receive appropriate compensation when we apply them in serving clients. As a world-class
professional services organisation, we have always maintained an appropriate balance among these three objectives. As we move forward in a technology-enabled environment that increasingly permits us to rapidly share and access knowledge electronically, it is important that we continue to maintain this balance. We also must continue our commitment to avoiding unauthorised reproduction of information or materials belonging to others and to maintaining the security of our intellectual capital. We must promote the sharing of knowledge across international boundaries. Lastly, we must be clear on responsibilities for knowledge management and quality.

AD maintains that Type 2 services cannot be sold to audit clients. The latter are customers already being served with Type 1 services but potential clients or targets for FD. AD executives protect their clients as they are duty-bound by confidentiality agreements. However, FD maintains that there are certain Type 2 services that can be sold to audit clients — they maintain this as is the case particularly in Denmark. Both these arguments are supported by the knowledge-sharing policy document.

Point 2 in the document cited above refers to confidentiality — the stand of AD department. The extract “generally avoid entering into agreements with clients that restrict our ability to share knowledge beyond what is required to protect client-confidential information” suggests that both AD and FD should refuse entering into agreements that restrict their ability to share knowledge. Either department could use this statement against the other if it is overly protective of its client. The confidentiality argument will only lead to more disputes since only the department protecting its client gets a share of the client knowledge. The confidentiality argument will only lead to more disputes since only the department protecting its client gets a share of the client’s knowledge which is held within the department if a need for raising capital arises or if a company wants to buy or sell a part or in full. This is a clear business opportunity for FD that MD services brings to FD’s doorstep. However, our discussions with FD professionals have shown that taking up business with starting companies is not cost-effective for FD. FD could maintain a database of solutions that can help FD in picking up the closest solution it has for a particular requirement at a startup-up company and then customise it to the client’s satisfaction. However, such a suggestion will take the discussion back to Malhotra’s (2003) Model 1 that has already been proven less applicable in FD’s case. Similarly, FD can share knowledge on targets that might be of interest to startup services. Also, FD and MD can share knowledge on industry with each other. All our interviews and informal conversations have proven this observation to be correct. FD and AD can leverage on the knowledge of relationships that MD services can provide due to its strategic position that helps it connect to the venture capital industry and private equity investment community. This is the knowledge on relationships in the market that FD will be most willing to take up.
As claimed by DiMaggio and Louch (1998), buyers tend to prefer social relations to make purchases of one-time items. According to them, within networks exchange reduces buyer risk by imposing cost on sellers who take advantage of opportunities to exploit advantages internal to the exchange. The commercial transaction is embedded in a multiplex network of ongoing interactions, so that the actors’ behaviour in the commercial exchange influences the way in which he or she is treated by many different actors across a range of interactions extending well into the future. This implies that buyers are more willing to buy such services from within their network. Seen from an FD perspective, it will be easier for the FD department to sell services if they have a relationship with the target. DiMaggio and Louch (1998) also state that people who transact with members of their social relations are more likely to report high levels of satisfaction with the product or service they receive. This, in turn, implies that from a sum total of such transactions, it is likely that FD will always end up with positive points. This will add up to both a larger network and positive future references and this, in turn, can potentially drive the business in an upward rising spiral.

Apart from personal networks, this analysis can be done on the basis of organisational networks. According to Uzzi (1996), organisation networks operate on a logic of exchange that differs from the logic of markets: ongoing social ties shape actors’ expectations and opportunities in ways that differ from the economic logic of market behaviour. The level of embeddedness in an exchange system produces opportunities and constraints that are particular to network forms of organisations and that result in outcomes not predicted by standard economic explanations. Figure 3 illustrates an example of MD and FD working on a network logic.

Figure 3 shows that MD services has a vast network of angel investors, venture capital companies, and private equity companies, which invest in companies that may be start-ups or later stage companies. MD services can regularly draw on the networks of its investors and feed any contacts that they may have to FD and AD. If FD was to leverage this network, it is very likely that in a small economy like Denmark, they will find relationships that help them grow their business. Following Uzzi (1996), embeddedness shifts actors’ motivations away from the narrow pursuit of immediate economic gains towards the enrichment of relationships through trust and reciprocity. Trust helps reduce transactional uncertainty and creates opportunities for the exchange of goods and services that are difficult to price or enforce contractually. Larson (1992) reported that “thicker information” on strategy, know-how and profit margins is

![Fig. 3. Utilising network relationships on the example of FD and MD.](image-url)
transferred through embedded ties, thus promoting learning and integrated production in ways that the exchange of only price data cannot. For both departments there is serious business potential in accepting knowledge on social networks from each other.

8. Conclusion
Knowledge sharing among the three departments studied in ConCop is hindered by a few important factors. One of them is the different nature of the everyday business activities in which the departments are engaged. FD operates in a more unstable business environment than AD and, therefore, the current IT-based KMS does not yield outcomes acceptable to FD. For its KM strategy, FD needs to differentiate between IT and KM and employ IT for sharing of explicit knowledge only. Other departments may find existing IT systems more suitable but still like FD, they should exploit the network-based knowledge.

The nature of the business of the three departments predisposes different requirements to the type of knowledge sought as well as different preferences to how the needed knowledge is obtained. We have identified three clusters of people in this respect. The first group sought knowledge to speed up certain processes. The second group was looking for standard templates to be used to save time to perform well-documented tasks. The third group was not looking for knowledge on a particular topic but for a peer who possessed the needed specific knowledge. Their cost of searching the database for knowledge, making sense of the document and then applying it to the situation at hand far exceeded the cost of finding and contacting the expert and taking first-hand advice.

A second barrier to cross-departmental knowledge sharing is the way codification and personalisation is utilised by the different departments. Knowledge sharing on industry through codification is difficult since the knowledge requirements of the departments differ. Knowledge sharing on industry and targets through personalisation is difficult because of confidentiality agreements with clients. Knowledge sharing on targets through codification was considered unfeasible.

Additionally, the current KMSs in ConCop heavily rely on IT databases, they are too structured and slow to provide new knowledge required by the departments. Inter-departmental interaction was found lacking more severely so in the cases of AD and FD. This was primarily due to confidentiality agreements. We also found that the mutual visibility of the departments to each other within ConCop was less than their visibility to their counterparts in other ConGlobal offices.

9. Proposed Solutions
If it is knowledge of networks that can drive the business, why is this knowledge not harnessed? We found a possible answer in an ongoing social networks based research project entitled “small world project” (Watts et al., 2002), according to which any individual can reach any other individual in the world in short chains of social ties. These authors point out that despite the “it is a small world after all” phenomenon and the “six degrees” theory of social connection, people still appear largely disconnected because they only have local information on networks. People tend to limit the members in their immediate group to a number that is cognitively manageable. If someone asks for an introduction to someone, we can often think only of our immediate group and if none of those people can help, then the chain breaks.

There is no methodical way of finding the person in the network. However, there are systems available that can be used to manage such relationships. Time Inc. (2003) states:

What started as a bit of Net-induced whimsy is rapidly spawning some of the most interesting business software on the planet. Call them social network applications — computer programs that analyze networks of people, their contacts, and even their ideas. The programs of everything from helping salespeople generate leads to ferreting out connections among criminals to matching people in sprawling corporations with other folks in-house who are working on similar projects. Social networking applies the power of the network to one of the most fundamental problems in all of business: finding the person who has the critical information you need, right when you need it. That is why business 2.0, a magazine from Fortune Group, Time Inc. has selected social networks as our Technology of the year for 2003.

With support from these new IT tools, it is possible to virtually scan all personal networks in an organisation to exploit the value in relationships. This new emerging field of social network analysis and tools, also called relationship capital management, is, in our view, an optimal tool to be employed to increase knowledge sharing between the departments. The best way to share industry knowledge would be to share competencies in a network. This would enable department teams to interact outside their closed group to bring in new information not only from their own groups in other offices, but also from other industry sources known to other departments. The
new knowledge from this interaction will help increase the respective groups’ situated expertise, which, in turn, will most likely increase group performance. It is also likely that increased group performance will make the departments more visible to each other. This can potentially build more confidence and trust among departments and will possibly in the future bring more revenues.

The IT systems we propose are related to sharing knowledge based on competencies and relationships, a kind of knowledge which is explicit and can be shared as suggested by Malhotra (2003) whereas the IT systems we discount, particularly in the case of FD, are systems trying to enable sharing tacit knowledge. Knowledge changes faster than the systems can keep up with. Moreover, the IT systems suggested are such that they can be kept locally, need no maintenance, are self-driven and are very simple. These systems do not need any user intervention for loading, running or maintaining. All these characteristics are in direct contrast of the characteristics of the IT systems currently employed in ConCop for sharing knowledge.

Bearing in mind that ConCop is an organisation dependent on employees’ ability to create new knowledge and on their willingness and ability to share knowledge with others, an alternative (or rather complementary to the IT-based solutions proposed above) mechanism for facilitating knowledge sharing among the three departments is experimenting with motivators for knowledge sharing. The importance of intrinsic motivation seems to be prevailing in knowledge-intensive organisations and, hence, it needs to be considered in ConCop’s context. Intrinsic motivation can be stimulated by, among others, raising organisational members’ sense of self-determination through encouraging participation and personal relationship (Osterloh and Frey, 2000). Additionally, ConCop may consider introducing extrinsic rewards for knowledge sharing. In such a case, management needs to be careful and alert to possible difficulties related to knowledge sharing as extrinsic may have a negative impact on individual and organisational performance in a long term. As suggested by Kohn (1993), employee incentive plans do not succeed in improving employee performance over the long term because the promise of rewards is manipulative, the competition for rewards inhibits cooperation and teamwork among employees and rewards discourage risk taking and creativity. Since research findings regarding the importance of extrinsic and intrinsic motivational mechanisms for knowledge sharing are inconsistent and often contradictory, it is up to the ConCop’s strategic management to implement those that fit with the company’s overall objectives in general and in terms of KM.
